

Association between dependent (post-caesarean endometritis & surgical site infection) and independent (Chlorhexidine vaginal cleansing) variables

	Chlorhexidine vaginal cleansing		OR	95% C.I for OR	P value
	Yes	No			
	156 (%)	144 (%)			
<i>Endometritis</i>					
Yes	8 (5.1)	19 (13.2)	0.356	0.151 – 0.840	0.018
No	148 (94.9)	125 (86.8)			
<i>Surgical site infection</i>					
Yes	19 (12.2)	23 (16.0)	0.730	0.379 – 1.405	0.346
No	137 (87.8)	121 (84.0)			

Table 3 shows that post-caesarean endometritis is significantly lower in those who had Chlorhexidine vaginal cleansing (P = 0.018). Participants who had Chlorhexidine vaginal cleansing were less likely to have post caesarean endometritis (OR = 0.356, 95% C.I = 0.151 – 0.840).
